**Welcome**

# Preface

This is a book created to be used for a statistical computing course at the undergraduate level.

# **Part I**

# **R Programming**

# 1 Basic R Programming

## 1.1 Introduction

This chapter focuses on the basics of R programming. While most of your statistical analysis will be done with R functions, it is important to have an idea of what is going on. Additionally, we will cover other topics that you may or may not need to know. The topics we will cover are:

1. Basic calculations in R
2. Types of Data
3. R Objects
4. R Functions
5. R Packages

## 1.2 Basic Calculations

This section focuses on the basic calculation that can be done in R. This is done by using different operators in R. The table below provides some of the basic operators R can use:

Operator	Description
+	Addition
-	Subtraction
*	Multiplication
/	Divides
^ or **	Exponentiate
?	Help Documentation

## 1.2.1 Calculator

### 1.2.1.1 Addition

To add numbers in R, all you need to use the `+` operator. For example  $2 + 2 = 4$ . When you type it in R you have:

```
2 + 2
```

```
[1] 4
```

When you ask R to perform a task, it prints out the result of the task. As we can see above, R prints out the number 4.

To add more than 2 numbers, you can simply just type it in.

```
2 + 2 + 2
```

```
[1] 6
```

This provides the number 6.

### 1.2.1.2 Subtraction

To subtract numbers, you need to use the `-` operator. Try  $4 - 2$ :

```
4 - 2
```

```
[1] 2
```

Try  $4 - 6 - 4$

```
4 - 6 - 4
```

```
[1] -6
```

Notice that you get a negative number.

Now try  $4 + 4 - 2 + 8$ :

```
4 + 4 - 2 + 8
```

```
[1] 14
```

### 1.2.1.3 Multiplication

To multiply numbers, you will need to use the `*` operator. Try `4 * 4`:

```
4 * 4
```

```
[1] 16
```

### 1.2.1.4 Division

To divide numbers, you can use the `/` operator. Try `9 / 3`:

```
9 / 3
```

```
[1] 3
```

### 1.2.1.5 Exponents

To exponentiate a number to the power of another number, you can use the `^` operator. Try `2^5`:

```
2^5
```

```
[1] 32
```

If you want to find  $e^2$ , you will use the `exp()` function. Try `exp(2)`:

```
exp(2)
```

```
[1] 7.389056
```

### 1.2.1.6 Roots

To take the n-th root of a value, use the `^` operator with the `/` operator to take the n-th root. For example, to take  $\sqrt[5]{32}$ , type `32^(1/5)`:

```
32^(1/5)
```

```
[1] 2
```

### 1.2.1.7 Logarithms

To take the natural logarithm of a value, you will use the `log()` function. Try `log(5)`:

```
log(5)
```

```
[1] 1.609438
```

If you want to take the logarithm of a different base, you will use the `log()` function with `base` argument. We will discuss this more in Section [1.4](#).

## 1.2.2 Comparing Numbers

Another important part of R is comparing numbers. When you compare two numbers, R will tell if the statement is **TRUE** or **FALSE**. Below are the different comparisons you can make:

Operator	Description
>	Greater Than
<	Less Than
>=	Greater than or equal
<=	Less than or equal
==	Equals
!=	Not Equals

### 1.2.2.1 Less than/Greater than

To check if one number is less than or greater than another number, you will use the `>` or `<` operators. Try `5 > 4`:

```
5 > 4
```

```
[1] TRUE
```

Notice that R states it's true. It evaluates the expression and tells you if it's true or not. Try `5 < 4`:

```
5 < 4
```

```
[1] FALSE
```

Notice that R tells you it is false.

#### 1.2.2.2 Less than or equal to/Greater than or equal to

To check if one number is less than or equal to/greater than or equal to another number, you will use the `>=` or `<=` operators. Try `5 >= 5`:

```
5 >= 5
```

```
[1] TRUE
```

Try `5 >= 4`:

```
5 >= 4
```

```
[1] TRUE
```

Try `5 <= 4`:

```
5 <= 4
```

```
[1] FALSE
```

#### 1.2.2.3 Equals and Not Equals

To check if 2 numbers are equal to each other, you can use the `==` operator. Try `3 == 3`:

```
3 == 3
```

```
[1] TRUE
```

Try `4 == 3`

```
3 == 4
```

```
[1] FALSE
```

Another way to see if 2 numbers are not equal to each other, you can use the `!=`. Try `3 != 4`:

```
3 != 4
```

```
[1] TRUE
```

Try `3 != 3`:

```
3 != 3
```

```
[1] FALSE
```

You may be asking why use `!=` instead of `==`. They both provides similar results. Well the reason is that you may need the `TRUE` output for analysis. One is only true when they are equal, while the other is true when they are not equal.

### 1.2.3 Help

The last operator we will discuss is the help operator `?`. If you want to know more about anything we talked about you can type `?` in front of a function and a help page will pop-up in your browser or in RStudio's 'Help' tab. For example you can type `?Arithmetic` or `?Comparison`, to review what we talked about. For other operators we didn't talk about use `?assignOps` and `?Logic`.

## 1.3 Types of Data

In R, the type of data, also known as class, we are using dictates how the programming works. For the most part, users will use *numeric*, *logical*, *POSIX* and *character* data types. Other types of data you may encounter are *complex* and *raw*. To obtain more information on them, use the `?` operator.

### 1.3.1 Numeric

The *numeric* class is the data that are numbers. Almost every analysis that you use will be based on the numeric class. To check if you have a numeric class, you just need to use the `is.numeric()` function. For example, try `is.numeric(5)`:

```
is.numeric(5)
```

```
[1] TRUE
```

Numeric classes are essentially *double* and *integer* types of data. For example a *double* data is essentially a number with decimal value. An *integer* data are whole numbers. Try `is.numeric(5.63)`, `is.double(5.63)` and `is.integer(5.63)`:

```
is.numeric(5.63)
```

```
[1] TRUE
```

```
is.double(5.63)
```

```
[1] TRUE
```

```
is.integer(5.63)
```

```
[1] FALSE
```

Notice how the value 5.63 is a *numeric* and *double* but not *integer*. Now let's try `is.numeric(7)`, `is.double(7)` and `is.integer(7)`:

```
is.numeric(7)
```

```
[1] TRUE
```

```
is.double(7)
```

```
[1] TRUE
```

```
is.integer(7)
```

```
[1] FALSE
```

Notice how the value 7 is also considered a *numeric* and *double* but not *integer*. This is because typing a whole number will be stored as a *double*. However, if we need to store an *integer*, we will need to type the letter “L” after the number. Try `is.numeric(7L)`, `is.double(7L)`, and `is.integer(7L)`:

```
is.numeric(7L)
```

```
[1] TRUE
```

```
is.double(7L)
```

```
[1] FALSE
```

```
is.integer(7L)
```

```
[1] TRUE
```

### 1.3.2 Logical

A *logical* class are data where the only value is TRUE or FALSE. Sometimes the data is coded as 1 for TRUE and 0 for FALSE. The data may also be coded as T or F. To check if data belongs in the *logical* class, you will need the `is.logical()` function. Try `is.logical(3 < 4)`:

```
is.logical(3 < 4)
```

```
[1] TRUE
```

This is same comparison from Section 1.2.2. The output was TRUE. Now R is checking whether the output is of a *logical* class. Since it is, R returns TRUE. Now try `is.logical(3 > 4)`:

```
is.logical(3 > 4)
```

```
[1] TRUE
```

The output is TRUE as well even though the condition `3 > 4` is FALSE. Since the output is a *logical* data type, it is a *logical* variable.

### 1.3.3 POSIX

The *POSIX* class are date-time data. Where the data value is a time component. The *POSIX* class can be very complex in how it is formatted. If you would like to learn more try `?POSIXct` or `?POSIXlt`. First, let's run `Sys.time()` to check what is today's date and time:

```
Sys.time()
```

```
[1] "2023-01-22 22:13:48 PST"
```

Now let's check if it's of POSIX class, you can use the `class()` function to figure out which class it is. Try `class(Sys.time())`:

```
class(Sys.time())
```

```
[1] "POSIXct" "POSIXt"
```

### 1.3.4 Character

A *character* value is where the data values follow a *string* format. Examples of *character* values are letters, words and even numbers. A *character* value is any value surrounded by quotation marks. For example, the phrase "Hello World!" is considered as one *character* value. Another example is if your data is coded with the actual words "yes" or "no". To check if you have *character* data, use the `is.character()` function. Try `is.character("Hello World!")`:

```
is.character("Hello World!")
```

```
[1] TRUE
```

Notice that the output says TRUE. *Character* values can be created with single quotations. Try `is.character('Hello World!')`:

```
is.character('Hello World!')
```

```
[1] TRUE
```

### 1.3.5 Complex Numbers

*Complex* numbers are data values where there is a real component and an imaginary component. The imaginary component is a number multiplied by  $i = \sqrt{-1}$ . To create a *complex* number, use the `complex()` function. To check if a number is complex, use the `is.complex()` function. Try the following to create a complex number `complex(1, 4, 5)`:

```
complex(1, 4, 5)
```

```
[1] 4+5i
```

Now try `is.complex(complex(1, 4, 5))`:

```
is.complex(complex(1, 4, 5))
```

```
[1] TRUE
```

### 1.3.6 Raw

You will probably never use raw data. I have never used raw data in R. To create a raw value, use the `raw()` or `charToRaw()` functions. Try `charToRaw('Hello World!')`:

```
charToRaw('Hello World!')
```

```
[1] 48 65 6c 6c 6f 20 57 6f 72 6c 64 21
```

To check if you have raw data, use the `is.raw()` function. Try `is.raw(charToRaw('Hello World!'))`:

```
is.raw(charToRaw('Hello World!'))
```

```
[1] TRUE
```

### 1.3.7 Missing

The last data class in R is missing data. The table below provides a brief introduction of the different types of missing data

Value	Description	Functions
NULL	These are values indicating an object is empty. Often used for functions with values that are undefined.	<code>is.null()</code>
NA	Stands for “Not Available”, used to indicate that the value is missing in the data.	<code>is.na()</code>
NaN	Stands for “Not an Number”. Used to indicate a missing number.	<code>is.nan()</code>
Inf and -Inf	Indicating an extremely large value or a value divided by 0.	<code>is.infinite()</code>

## 1.4 R Functions

An R function is the procedure that R will execute to certain data. For example, the `log(x)` is an R function. It takes the value `x` and provides you the natural logarithm. Here `x` is known as an argument which needs to be specified to us the `log()` function. Find the `log(x = 5)`

```
log(x = 5)
```

```
[1] 1.609438
```

Another argument for the `log()` function is the `base` argument. With the previous code, we did not specify the `base` argument, so R makes the `base` argument equal to the number  $e$ . If you want to use the common log with base 10, you will need to set the `base` argument equal to 10.

Try `log(x = 5, base = 10)`

```
log(x = 5, base = 10)
```

```
[1] 0.69897
```

Now try `log(5,10)`

```
log(5,10)
```

```
[1] 0.69897
```

Notice that it provides the same value. This is because R can set arguments based on the values position in the function, regardless if the arguments are specified. For `log(5,10)`, R thinks that 5 corresponds to the first argument `x` and 10 is the second argument `base`.

To learn more about a functions, use the `?` operator on the function: `?log`.

## 1.5 R Objects

R objects are where most of your data will be stored. An R object can be thought of as a container of data. Each object will share some sort of characteristics that will make the unique for different types of analysis.

### 1.5.1 Assigning objects

To create an R object, all we need to do is assign data to a variable. The variable is the name of the R object. it can be called anything, but you can only use alphanumeric values, underscore, and periods. To assign a value to a variable, use the `<-` operator. This is known as a left assignment. Kinda like an arrow pointing left. Try assigning 9 to 'x' (`x <- 9`):

```
x <- 9
```

To see if `x` contains 9, type `x` in the console:

```
x
```

```
[1] 9
```

Now `x` can be treated as data and we can perform data analysis on it. For example, try squaring it:

```
x^2
```

```
[1] 81
```

You can use any mathematical operation from the previous sections. Try some other operations and see what happens.

The output R prints out can be stored in a variable using the assign operator, `<-`. Try storing `x^3` in a variable called `x_cubed`:

```
x_cubed <- x^3
```

To see what is stored in `x_cubed` you can either type `x_cubed` in the console or use the `print()` function with `x_cubed` inside the parenthesis.

```
x_cubed
```

```
[1] 729
```

```
print(x_cubed)
```

```
[1] 729
```

## 1.5.2 Vectors

A vector is a set data values of a certain length. The R object `x` is considered as a numerical vector (because it contains a number) with the length 1. To check, try `is.numeric(x)` and `is.vector(x)`:

```
is.numeric(x)
```

```
[1] TRUE
```

```
is.vector(x)
```

```
[1] TRUE
```

Now let's create a logical vector that contains 4 elements (have it follow this sequence: T, F, T, F) and assign it to `y`. To create a vector use the `c()`<sup>1</sup> function and type all the values and separating them with columns. Type `y <- c(T, F, T, F)`:

```
y <- c(T, F, T, F)
```

Now, lets see how `y` looks like. Type `y`:

```
y
```

```
[1] TRUE FALSE TRUE FALSE
```

Now lets see if it's a logical vector:

```
is.logical(y)
```

```
[1] TRUE
```

```
is.vector(y)
```

```
[1] TRUE
```

Fortunately, this vector is really small to count how many elements it has, but what if the vector is really large? To find out how many elements a vector has, use the `length()` function. Try `length(y)`:

---

<sup>1</sup>The `c()` function allows you to put any data type and as many values as you wish. The only condition of a vector is that it must be the same data type.

```
length(y)
```

```
[1] 4
```

### 1.5.3 Matrices

A matrix can be thought as a square or rectangular grid of data values. This grid can be constructed can be any size. Similar to vectors they must contain the same data type. The size of a matrix is usually denoted as  $n \times k$ , where  $n$  represents the number of rows and  $k$  represents the number of columns. To get a rough idea of how a matrix may look like, type `matrix(rep(1,12), nrow = 4, ncol = 3)`<sup>2</sup>:

```
matrix(rep(1, 12), nrow = 4, ncol = 3)
```

	[,1]	[,2]	[,3]
[1,]	1	1	1
[2,]	1	1	1
[3,]	1	1	1
[4,]	1	1	1

Notice that this is a  $4 \times 3$  matrix. Each element in the matrix has the value 1. Now try this `matrix(rbinom(12,1.5), nrow = 4, ncol = 3)`<sup>3</sup>:

```
matrix(rbinom(12, 1, .5), nrow = 4, ncol = 3)
```

	[,1]	[,2]	[,3]
[1,]	0	0	1
[2,]	1	1	0
[3,]	0	0	1
[4,]	1	0	0

---

<sup>2</sup>The function `rep()` creates a vector by repeating a value for a certain length. `rep(1,12)` creates a vector of length 12 with each element being 1. We use the `nrow` and `ncol` arguments in the function to specify the number of rows and columns, respectfully.

<sup>3</sup>The `rbinom()` function generates binomial random variables and stores them in a vector. `rbinom(12,1,5)` This creates 12 random binomial numbers with parameter  $n = 1$  and  $p = 0.5$ .

Your matrix may look different, but that is to be expected. Notice that some elements in a matrix are 0's and some are 1's. Each element in a matrix can hold any value.

An alternate approach to creating matrices is with the use of `rbind()` and `cbind()` functions. Using 2 vectors, and matrices, of the same length, the `rbind()` will append the vectors together by each row. Similarly, the `cbind()` function will append vectors, and matrices, of the same length by columns.

```
x <- 1:4
y <- 5:8
z <- 9:12
cbind(x, y, z)
```

```
      x y  z
[1,] 1 5  9
[2,] 2 6 10
[3,] 3 7 11
[4,] 4 8 12
```

```
rbind(x, y, z)
```

```
  [,1] [,2] [,3] [,4]
x     1     2     3     4
y     5     6     7     8
z     9    10    11    12
```

If you want to create a matrix of a specific size without any data, you can use the `matrix()` function and only specify the `nrow` and `ncol` arguments. Here we are creating a  $5 \times 11$  empty matrix:

```
matrix(nrow = 5, ncol = 11)
```

```
      [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11]
[1,]   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA
[2,]   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA
[3,]   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA
[4,]   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA
[5,]   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA   NA
```

Lastly, if you need to find out the dimensions of a matrix, you can use `dim()` function on a matrix:

```
dim(matrix(nrow = 5, ncol = 11))
```

```
[1] 5 11
```

This will return a vector of length 2 with the first element being the number of rows and the second element being the number of columns.

### 1.5.4 Arrays

Matrices can be considered as a 2-dimensional block of numbers. An array is an n-dimensional block of numbers. While you may never need to use an array for data analysis. It may come in handy when programming by hand. To create an array, use the `array()` function. Below is an example of a  $3 \times 3 \times 3$  with the numbers 1, 2, and 3 representing the 3rd dimension stored in an R object called `first_array`<sup>4</sup>.

```
(first_array <- array(c(rep(1, 9), rep(2, 9), rep(3, 9)),  
                      dim=c(3,3,3)))
```

```
, , 1
```

	[,1]	[,2]	[,3]
[1,]	1	1	1
[2,]	1	1	1
[3,]	1	1	1

```
, , 2
```

	[,1]	[,2]	[,3]
[1,]	2	2	2
[2,]	2	2	2
[3,]	2	2	2

```
, , 3
```

---

<sup>4</sup>Notice the code is surrounded by parenthesis. This tells R to store the array and print out the results. You can surround code with parenthesis every time you create an object to also print what is stored.

```

      [,1] [,2] [,3]
[1,]    3    3    3
[2,]    3    3    3
[3,]    3    3    3

```

### 1.5.5 Data Frames

Data frames are similar to data set that you may encounter in an excel file. However, there are a couple of differences. First, each row represents an observation, and each column represents a characteristic of the observation. Additionally, each column in a data frame will be the same data type. To get an idea of what a data frame looks like, try `head(iris)` <sup>5</sup>:

```
head(iris)
```

```

      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
1             5.1           3.5          1.4          0.2  setosa
2             4.9           3.0          1.4          0.2  setosa
3             4.7           3.2          1.3          0.2  setosa
4             4.6           3.1          1.5          0.2  setosa
5             5.0           3.6          1.4          0.2  setosa
6             5.4           3.9          1.7          0.4  setosa

```

In the data frame, the rows indicate a specific observation and the columns are the values of a variable. In terms of the `iris` data set, we can see that row 1 is a specific flower that has a sepal length of 5.1. We can also see that flower 1 has other characteristics such as sepal width and petal length. Lastly, there are results for the other flowers.

Now try `tail(iris)`:

```
tail(iris)
```

```

      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
145             6.7           3.3          5.7          2.5 virginica
146             6.7           3.0          5.2          2.3 virginica
147             6.3           2.5          5.0          1.9 virginica
148             6.5           3.0          5.2          2.0 virginica
149             6.2           3.4          5.4          2.3 virginica
150             5.9           3.0          5.1          1.8 virginica

```

---

<sup>5</sup>The `head()` function just tells R to only print the top few components of the data frame.

The `tail()` function provides the last 6 rows of the data frame.

Lastly, if you are interested in viewing a specific variable (column) from a data frame, you can use the `$` operator to specify which variable from a specific data frame. For example, if we are interested in observing the `Sepal.Length` variable from the `iris` data frame, we will type `iris$Sepal.Length`:

```
iris$Sepal.Length
```

```
[1] 5.1 4.9 4.7 4.6 5.0 5.4 4.6 5.0 4.4 4.9 5.4 4.8 4.8 4.3 5.8 5.7 5.4 5.1
[19] 5.7 5.1 5.4 5.1 4.6 5.1 4.8 5.0 5.0 5.2 5.2 4.7 4.8 5.4 5.2 5.5 4.9 5.0
[37] 5.5 4.9 4.4 5.1 5.0 4.5 4.4 5.0 5.1 4.8 5.1 4.6 5.3 5.0 7.0 6.4 6.9 5.5
[55] 6.5 5.7 6.3 4.9 6.6 5.2 5.0 5.9 6.0 6.1 5.6 6.7 5.6 5.8 6.2 5.6 5.9 6.1
[73] 6.3 6.1 6.4 6.6 6.8 6.7 6.0 5.7 5.5 5.5 5.8 6.0 5.4 6.0 6.7 6.3 5.6 5.5
[91] 5.5 6.1 5.8 5.0 5.6 5.7 5.7 6.2 5.1 5.7 6.3 5.8 7.1 6.3 6.5 7.6 4.9 7.3
[109] 6.7 7.2 6.5 6.4 6.8 5.7 5.8 6.4 6.5 7.7 7.7 6.0 6.9 5.6 7.7 6.3 6.7 7.2
[127] 6.2 6.1 6.4 7.2 7.4 7.9 6.4 6.3 6.1 7.7 6.3 6.4 6.0 6.9 6.7 6.9 5.8 6.8
[145] 6.7 6.7 6.3 6.5 6.2 5.9
```

### 1.5.6 Lists

To me a list is just a container that you can store practically anything. It is compiled of elements, where each element contains an R object. For example, the first element of a list may contain a data frame, the second element may contain a vector, and the third element may contain another list. It is just a way to store things.

To create a list, use the `list()` function. Create a list compiled of first element with the `mtcars` data set, second element with a vector of zeros of size 4, and a matrix  $3 \times 3$  identity matrix<sup>6</sup>. Store the list in an object called `list_one`:

```
list_one <- list(mtcars, rep(0, 4),
                diag(rep(1, 3)))
```

Type `list_one` to see what pops out:

```
list_one
```

---

<sup>6</sup>An identity matrix is a matrix where the diagonal elements are 1 and the non-diagonal elements are 0

```
[[1]]
```

Lotus Europa	30.4	4	95.1	113	3.77	1.513	16.90	1	1	5	2
Ford Pantera L	15.8	8	351.0	264	4.22	3.170	14.50	0	1	5	4
Ferrari Dino	19.7	6	145.0	175	3.62	2.770	15.50	0	1	5	6
Maserati Bora	15.0	8	301.0	335	3.54	3.570	14.60	0	1	5	8
Volvo 142E	21.4	4	121.0	109	4.11	2.780	18.60	1	1	4	2

```
[[2]]
```

```
[1] 0 0 0 0
```

```
[[3]]
```

	[,1]	[,2]	[,3]
[1,]	1	0	0
[2,]	0	1	0
[3,]	0	0	1

Each element in the list is labeled as a number. It is more useful to have the elements named. An element is named by typing the name in quotes followed by the = symbol before your object in the `list()` function (`mtcars=mtcars`).

```
list_one <- list(mtcars = mtcars,
               vector = rep(0, 4),
               identity = diag(rep(1, 3)))
```

Here I am creating an object called `list_one`, where the first element is `mtcars` labeled `mtcars`, the second element is a vector of zeros labeled `vector` and the last element is the identity matrix labeled `identity`.

Now create a new list called `list_two` and store `list_one` labeled as `list_one` and `first_array` labeled as `array`.

```
(list_two <- list(list_one = list_one,
                 array = first_array))
```

`$list_one`

`$list_one$mtcars`

## 1.6 R Packages

As I stated before, R can be extended to do more things, such as create this tutorial. This is done by installing R packages. An R package can be thought of as extra software. This allows you to do more with R. To install an R package, you will need to use `install.packages("NAME_OF_PACKAGE")`. Once you install it, you do not need to install it again. To use the R package, use `library("NAME_OF_PACKAGE")`. This allows you to load the package in R. You will need to load the package every time you start R. For more information, please watch the video: <https://vimeo.com/203516241>.

## 2 Control Flow

### 2.0.1 Vectors

In the Section [1.5](#), we discussed about different types of R objects. For example, a vector can be a certain data type with a set number of elements. Here we construct a vector called `x` increasing from -5 to 5 by one unit:

```
(x <- -5:5)
```

```
[1] -5 -4 -3 -2 -1  0  1  2  3  4  5
```

The vector `x` has 11 elements. If I want to know what the 6th element of `x`, I can index the 6th element from a vector. To do this, we use `[]` square brackets on `x` to index it. For example, we index the 6th element of `x`:

```
x[6]
```

```
[1] 0
```

When ever we use `[]` next to an R object, it will print out the data to a specific value inside the square brackets. We can index an R object with multiple values:

```
x[1:3]
```

```
[1] -5 -4 -3
```

```
x[c(3,9)]
```

```
[1] -3  3
```

Notice how the second line uses the `c()`. This is necessary when we want to specify non-contiguous elements. Now let's see how we can index a matrix

## 2.0.2 Matrices

A matrix can be indexed the same way as a vector using the `[]` brackets. However, since the matrix is a 2-dimensional objects, we will need to include a comma to represent the different dimensions: `[,]`. The first element indexes the row and the second element indexes the columns. To begin, we create the following  $4 \times 3$  matrix:

```
(x <- matrix(1:12, nrow = 4, ncol = 3))
```

	[,1]	[,2]	[,3]
[1,]	1	5	9
[2,]	2	6	10
[3,]	3	7	11
[4,]	4	8	12

Now to index the element at row 2 and column 3, use `x[2, 3]`:

```
x[2, 3]
```

```
[1] 10
```

We can also index a specific row and column:

```
x[2,]
```

```
[1] 2 6 10
```

```
x[,3]
```

```
[1] 9 10 11 12
```

## 2.0.3 Data Frames

There are several ways to index a data frame, since it is in a matrix format, you can index it the same way as a matrix. Here are a couple of examples using the `mtcars` data frame.

```
mtcars[,2]
```

```
[1] 6 6 4 6 8 6 8 4 4 6 6 8 8 8 8 8 8 4 4 4 4 8 8 8 8 4 4 4 8 6 8 4
```

```
mtcars[2,]
```

```
      mpg cyl disp  hp drat   wt  qsec vs am gear carb
Mazda RX4 Wag  21   6  160 110   3.9 2.875 17.02  0  1    4    4
```

However, a data frame has labeled components, variables, we can index the data frame with the variable names within the brackets:

```
mtcars[, "cyl"]
```

```
[1] 6 6 4 6 8 6 8 4 4 6 6 8 8 8 8 8 8 4 4 4 4 8 8 8 8 4 4 4 8 6 8 4
```

Lastly, a data frame can be indexed to a specific variable using the `$` notation as described in Section 1.5.5.

## 2.0.4 Lists

As described in Section 1.5.6, lists contain elements holding different R objects. To index a specific element of a list, you will use `[[ ]]` double brackets. Below is a toy list:

```
toy_list <- list(mtcars = mtcars,
                vector = rep(0, 4),
                identity = diag(rep(1, 3)))
```

To access the second element, vector element, you can type `toy_list[[2]]`

```
toy_list[[2]]
```

```
[1] 0 0 0 0
```

Since the elements are labeled within the list, you can place the label in quotes inside `[[ ]]`:

```
toy_list[["vector"]]
```

```
[1] 0 0 0 0
```

The element can be accessed using the `$` notation with a list:

```
toy_list$vector
```

```
[1] 0 0 0 0
```

Lastly, you can further index the list if needed, we can access the `mpg` variable in `mtcars` from the `toy_list`:

```
toy_list$mtcars$mpg
```

```
[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4
[16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7
[31] 15.0 21.4
```

```
toy_list[["mtcars"]]$mpg
```

```
[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4

```

## 2.1 If/Else Statements

In R, there are control flow functions that will dictate how a program will be executed. The first set of functions we will talk about are `if` and `else` statements. First, the `if` statement will evaluate a task, If the conditions is satisfied, yields `TRUE`, then it will conduct a certain task, if it fails, yields `FALSE`, the `else` statement will guide it to a different task. Below is a general format:

### Important Concept

```
if (condition) {  
  TRUE task  
} else {  
  FALSE task  
}
```

### 2.1.1 Example

Below is an example where we generate `x` from a standard normal distribution and print the statement 'positive' or 'non-positive' based on the condition `x > 0`.

```
x <- rnorm(1)  
  
## if statements  
if (x > 0){  
  print("Positive")  
} else {  
  print("Non-Positive")  
}
```

```
[1] "Non-Positive"
```

What if we want to print the statement 'negative' as well if the value is negative? We will then need to add another `if` statement after the `else` statement since `x > 0` only lets us know if the value is positive.

```
x <- rnorm(1)  
  
if (x > 0){
```

```
    print("Positive")
  } else if (x < 0) {
    print("Negative")
  }
```

```
[1] "Positive"
```

Above, we add the `if` statement with condition (`x < 0`) indicating if the number is negative. Lastly, if `x` is ever 0, we will want R to let us know it is 0. We can achieve this by adding one last `else` statement:

```
x <- rnorm(1)

if (x > 0){
  print("Positive")
} else if (x < 0) {
  print("Negative")
} else {
  print("Zero")
}
```

```
[1] "Negative"
```

## 2.2 for loops

A `for` loop is a way to repeat a task a certain amount of times. Every time a loop repeats a task, we state it is an iteration of the loop. For each iteration, we may change the inputs by a certain way, either from an indexed vector, and repeat the task. The general anatomy of a loop looks like:

### Important Concept

```
for (i in vector){
  perform task
}
```

The `for` statement indicates that you will repeat a task inside the brackets. The `i` in the parenthesis controls how the task will be completed. The `in` statement tells R where `i` can

look for the values, and `vectorr` is a vector R object that contains the values `i` can be. It also controls how many times the task will be repeated based on the length of the vector.

Learning about a loop is quite challenging, my recommendation is to read the section below and break the example code so you can understand how a `for` loop works.

### 2.2.1 Basic for loop

Let's say we want R to print one to five separately. We can achieve this by repeating the `print()` 5 times.

```
print(1); print(2); print(3); print(4); print(5)
```

```
[1] 1
```

```
[1] 2
```

```
[1] 3
```

```
[1] 4
```

```
[1] 5
```

However, this takes quite awhile to type up. Let's try to achieve the same task using a `for` loop.

```
for (i in 1:5){  
  print(i)  
}
```

```
[1] 1
```

```
[1] 2
```

```
[1] 3
```

```
[1] 4
```

```
[1] 5
```

Here, `i` will take a value from the vector `1:5`,<sup>1</sup> Then, R will print out what the value of `i` is.

Now, let's try another example with letters. To begin, create a new vector called `letters_10` containing the first 10 letters of the alphabet. Use the vector `letters` to construct the new vector.

```
letters_10 <- letters[1:10]
```

Now, we will use a loop to print out the first 10 letters:

```
for (i in 1:10) {  
  print(letters_10[i])  
}
```

```
[1] "a"  
[1] "b"  
[1] "c"  
[1] "d"  
[1] "e"  
[1] "f"  
[1] "g"  
[1] "h"  
[1] "i"  
[1] "j"
```

Here, we have `i` take on the values 1 through 10. Using those values, we will index the vector `letters_10` by `i`. The resulting letter will then be printed. This task repeated 10 times.

Lastly, we can replace `1:10` by `letters_10` instead:

```
for (i in letters_10){  
  print(i)  
}
```

```
[1] "a"  
[1] "b"  
[1] "c"  
[1] "d"  
[1] "e"  
[1] "f"
```

---

<sup>1</sup>Type this in the console to see what it is.

```
[1] "g"
[1] "h"
[1] "i"
[1] "j"
```

This is because `letters_10` are the values that we want to print and `i` takes on the value of `letters_10` each time.

## 2.2.2 Nested for loops

A nested `for` loop is a loop that contain a loop within. Below is an example of 3 `for` loops nested within each other. Below is a general example:

### Important Concept

```
for (i in vector_1) {
  for (ii in vector_2) {
    for (iii in vector_3) {
      perform task
    }
  }
}
```

As an example, we will use the `greekLetter::`<sup>2</sup> and use the `greek_vector` vector to obtain greek letters in R. Lastly, create a vector called `greek_10`.

```
library(greekLetters)
greek_10 <- greek_vector[1:10]
```

For this example, we want R to print “a” and “α” together as demonstrated below<sup>3</sup>:

```
print(paste0(letters_10[1], greek_10[1]))
```

```
[1] "a "
```

Now let’s repeat this process to print all possible combinations of the first 3 letters and 3 greek letters:

---

<sup>2</sup>`install.packages(greekLetters)`

<sup>3</sup>We will need to use `paste0()` to combine the letters together.

```

for (i in 1:3){
  for (ii in 1:3){
    print(paste0(letters_10[i], greek_10[ii]))
  }
}

```

```

[1] "a "
[1] "a "
[1] "a "
[1] "b "
[1] "b "
[1] "b "
[1] "c "
[1] "c "
[1] "c "

```

## 2.3 break

A **break** statement is used to stop a loop midway if a certain condition is met. A general setup of **break** statement goes as follows:

### Important Concept

```

for (i in vector){
  if (condition) {break}
  else {
    task
  }
}

```

As you can see there is an **if** statement in the loop. This is used to tell R when to break the loop. If the **if** statement was not there, then the loop will break without iterating.

To demonstrate the **break** statement, we will simulate from a  $N(1, 1)$  until we have 30 positive numbers or we simulate a negative number.

```

x <- rep(NA, length = 30)

for (i in seq_along(x)){

```

```

y <- rnorm(1,1)
if (y<0) {
  break
}
else {
  x[i] <- y
}
}
print(x)

```

```

[1] 2.0787655 1.6360843 0.2994991 0.6490530      NA      NA      NA
[8]      NA      NA      NA      NA      NA      NA      NA
[15]      NA      NA      NA      NA      NA      NA      NA
[22]      NA      NA      NA      NA      NA      NA      NA
[29]      NA      NA

```

```
print(y)
```

```
[1] -0.02507405
```

Notice that the vector does not get filled up all the way, that is because the loop will break once a negative number is simulated

## 2.4 next

Similar to the **break** statement, the **next** statement is used in loops that will tell R to move on to the next iteration if a certain condition is met.

### Important Note

```

for (i in vector){
  if (condition) {
    next
  } else {
    task
  }
}

```

The main difference here is that a **next** statement is used instead of a **break** statement.

Going back to simulating positive numbers, we will use the same setup but change it to a **next** statement.

```
x <- rep(NA,length = 30)

for (i in seq_along(x)){
  y <- rnorm(1,1)
  if (y<0) {
    next
  }
  else {
    x[i] <- y
  }
}
print(x)
```

```
[1] 1.5527741 0.8855561 0.3610046 1.9779432 0.9413717      NA 0.6667810
[8] 2.9277219 1.4730954 0.8043093 0.7859875 3.1748935 1.4574687      NA
[15] 1.9467555 1.2657363 1.1368128 1.2656183 0.7593004 1.0984954 0.4714110
[22] 0.8462918 0.6780324 1.7229675 1.7653550 0.2522486 0.3166376 1.8365824
[29] 1.2250506 0.3047977
```

As you can see, the vector contains missing values, these were the iterations that a negative number was simulated.

## 2.5 while loop

The last loop that we will discuss is a while loop. The while loop is used to keep a loop running until a certain condition is met. To construct a while loop, we will use the **while** statement with a condition attached to it. In general, a while loop will have the following format:

### Important Concept

```
while (condition) {
  task
  update condition
}
```

Above, we see that the `while` statement is used followed by a condition. Then the loop will complete its task and update the condition. If the condition yields a `FALSE` value, then the loop will stop. Otherwise, it will continue.

### 2.5.1 Basic while loops

To implement a basic `while` loop, we will work on the previous example of simulating positive numbers. We want to simulate 30 positive numbers from  $N(0, 1)$  until we have 30 values. Here, our condition is that we need to have 30 numbers. Therefore we can use the following code to simulate the values:

```
x <- c()
size <- 0
while (size < 30){
  y <- rnorm(1)
  if (y > 0) {
    x <- c(x, y)
  }
  size <- length(x)
}
print(size)
```

```
[1] 30
```

```
print(x)
```

```
[1] 1.50524472 2.31090627 0.44554041 1.10935651 1.63961115 0.11356579
[7] 0.43924753 0.55274957 0.08432888 0.45178630 1.88027237 0.20262722
[13] 1.31490524 3.40905624 1.57526945 0.98816146 0.36066813 1.39991080
[19] 0.67085417 0.18602281 0.31820984 0.40769929 0.56970001 0.45415937
[25] 1.25814284 0.40280256 0.42012018 0.07271380 0.10612265 1.13623356
```

Notice that we do not use an `else` statement. This is because we do not need R to complete a task if the condition fails.

### 2.5.2 Infinite while loops

With while loops, we must be weary about potential infinite loops. This occurs when the condition will never yield a `FALSE` value. Therefore, R will never stop the loop because it does not know when to do this.

For example, let's say we are interested if  $y = \sin(x)$  will converge to a certain value. As you know it will not converge to a certain value; however, we can construct a while loop:

```
x <- 1
diff <- 1
while (diff > 1e-20) {
  old_x <- x
  x <- x + 1
  diff <- abs(sin(x) - sin(old_x))
}
print(x)
print(diff)
```

My condition above is to see if the absolute difference between sequential values is smaller than  $10^{-20}$ . As you may know, the absolute difference will never become that small. Therefore, the loop will continue on without stopping.

To prevent an infinite while loop, we can add a counter to the condition statement. This counter will also need to be true for the loop to continue. Therefore, we can arbitrarily stop it when the loop has iterated a certain amount of times. We just need to make sure to add one to the counter every time it iterates it. Below is the code that adds a counter to the while loop:

```
x <- 1
counter <- 0
diff <- 1
while (diff > 1e-20 & counter < 10^3) {
  old_x <- x
  x <- x + 1
  diff <- abs(sin(x) - sin(old_x))
  counter <- counter + 1
}
print(x)
```

[1] 1001

```
print(diff)
```

```
[1] 0.09311106
```

```
print(counter)
```

```
[1] 1000
```

## 3 Functional Programming

### 3.1 Functions

The functionality in R is what makes it completely powerful compared to other statistical software. There are several pre-built functions, and you can extend R's functionality further with the use of R Packages.

#### 3.1.1 Built-in Functions

There are several available functions in R to conduct specific statistical methods. The table below provides a set of commonly used functions:

Functions	Description
<code>aov()</code>	Fits an ANOVA Model
<code>lm()</code>	Fits a linear model
<code>glm()</code>	Fits a general linear model
<code>t.test()</code>	Conducts a t-test

Several of these functions have help documentation that provide the following sections:

Section	Description
Description	Provides a brief introduction of the function
Usage	Provides potential usage of the function
Arguments	Arguments that the function can take
Details	An in depth description of the function
Value	Provides information of the output produced by the function
Notes	Any need to know information about the function
Authors	Developers of the function
References	References to the model and function
See Also	Provide information of supporting functions
Examples	Examples of the function

To obtain the help documentation of each function, use the `?` operator and function name in the console pane.

### 3.1.2 Generic Functions

Commonly used functions, such as `summary()` and `plot()`, are considered generic functions where their functionality is determined by the class of an R object. For example, the `summary()` is a generic for several types of functions: `summary.aov()`, `summary.lm()`, `summary.glm()`, and many more. Therefore, the appropriate function is needed depending the type of R object. This is where generic functions come in. We can use a generic function, ie `summary()`, to read the type of object and then apply to correct procedure to the object.

### 3.1.3 User-built Functions

While R has many capable functions that can be used to analyze your data, you may need to create a custom function for specific needs. For example, if you find yourself writing the same to repeat a task, you can wrap the code into a user-built function and use it for analysis.

To create a user-built function, you will using the `function()` to create an R object that is a function. To use the function Inside the `function()` parantheses, write the arguments that need to specified for your function.

#### 3.1.3.1 Anatomy

In general function we construct a function with the following anatomy:

```
name_of_function <- function(data_1, data_2 = NULL,
                             argument_1, argument_2 = TRUE, argument_3 = NULL,
                             ...){
  # Conduct Task
  # Conduct Task
  output_object <- Tasks
  return(output_object)
}
```

Here, we are creating an R function called `name_of_function` that will take the following arguments: `data_1`, `data_2`, `argument_1`, `argument_2`, `argument_3`, and `...`. From this function, it requires us to supply data for `data_1` and `argument_1`. Arguments `data_2` and `argument_3` are not required, but can be utilized in the function if necessary. Argument `argument_2` is also required for the function, but it has a default setting (in this case `TRUE`) if it is not specified. Lastly, the `...` argument allows you to pass other arguments to R built

in functions if they are present. For example, we may use the `plot()` to create graphics and want to manipulate the output plot further, but do not want to specify the arguments in the user-based function.

In the function itself, we will complete the necessary tasks and then use the `return()` to return the output.

### 3.1.3.2 Example

To begin, let's create a function that squares any value:

```
x_square <- function(x){x^2}
```

Above, I am creating a new function called `x_square` and it will take values of `x` and square it. Here are a couple of examples of `x_square()`:

```
x_square(4)
```

```
[1] 16
```

```
x_square(5)
```

```
[1] 25
```

The `mtcars` data set has several numeric variables that can be used for analysis. Let's say we want to apply a function (`x_square()`) to the sum of a specific variable and return the value. Then let's further complicate the function by allowing the sum of 2 variables, take the log of the sum and dividing the value if necessary. Below is the code for such function called `summing`:

```
summing <- function(vec1, vec2 = NULL, FUN, log_val = FALSE, divisor_val = NULL){  
  FUN <- match.fun(FUN)  
  wk_vec <- c(vec1, vec2)  
  fun_sum_val <- FUN(sum(wk_vec))  
  lval <- NULL  
  if (isTRUE(log_val)){  
    lval <- log(fun_sum_val)  
  } else {  
    lval <- fun_sum_val  
  }  
}
```

```

    }
    if (!is.null(divisor_val)){
      dval <- divisor_val
    } else {dval <- 1}
    output <- lval/dval
    return(output)
  }

```

Now let's try obtaining the

```
sum(mtcars$mpg)^2
```

```
[1] 413320.4
```

```
summing(mtcars$mpg, FUN = x_square)
```

```
[1] 413320.4
```

```
log(sum(c(mtcars$mpg,mtcars$disp))^2)
```

```
[1] 17.98088
```

```
summing(mtcars$mpg, mtcars$disp, x_square, T)
```

```
[1] 17.98088
```

```
log(sum(c(mtcars$mpg,mtcars$disp))^2)/5
```

```
[1] 3.596177
```

```
summing(mtcars$mpg, mtcars$disp, x_square, T, 5)
```

```
[1] 3.596177
```

## 3.2 \*apply Functions

\*apply functions are used to iterate a function through a set of elements in a vector, matrix, or list. This will then return a vector or list depending on what is requested.

### 3.2.1 `apply()`

The `apply()` is used to apply a function to the margins of an array or matrix. It will iterate between the elements, apply a function to the data, and return a vector, array or list if necessary. To use the `apply()`, you will need to specify three arguments, **X** or the array, **MARGIN** which margin to apply the function on, and **FUN** the function.

Below we calculate the row means and column means using the `apply` function for a  $5 \times 4$  matrix containing the elements 1 through 20:

```
x <- matrix(1:20, nrow = 5, ncol = 4)

# Row Means
apply(x, 1, mean)
```

```
[1]  8.5  9.5 10.5 11.5 12.5
```

```
# Col Means
apply(x, 2, mean)
```

```
[1]  3  8 13 18
```

### 3.2.2 `sapply()`

### 3.2.3 `lapply()`

## 3.3 Anonymous Functions

## 4 Scripting and Piping in R

### 4.1 Commenting

A comment is

### 4.2 Scripting

### 4.3 Piping

### 4.4 Keyboard Shortcuts

Below is a list of recommended keyboard shortcuts:

Shortcut	Windows/Linux	Mac
%>%	Ctrl+Shift+M	Cmd+Shift+M
Run Current Line	Ctrl+Enter	Cmd+Return
Knit Document	Ctrl+Shift+K	Cmd+Shift+K
Add Cursor Below	Ctrl+Alt+Down	Cmd+Alt+Down
Comment Line	Ctrl+Shift+C	Cmd+Shift+C

I recommend modify these keyboard shortcuts.

Shortcut	Windows/Linux	Mac
%in%	Ctrl+Shift+I	Cmd+Shift+I
%%\$%	Ctrl+Shift+D	Cmd+Shift+D
%T>%	Ctrl+Shift+T	Cmd+Shift+T

Note you will need to install the `extraInserts` package:

```
remotes::install_github('konradzdeb/extraInserts')
```

## **13 Data Manipulation**

# 14 Data Summarization

## 14.1 Descriptive Statistics

Here, we will go over some of the basic syntax to obtain basic statistics. We will use the variables `mpg` and `cyl` from the `mtcars` data set. To view the data set use the `head()`:

```
head(mtcars)
```

	mpg	cyl	disp	hp	drat	wt	qsec	vs	am	gear	carb
Mazda RX4	21.0	6	160	110	3.90	2.620	16.46	0	1	4	4
Mazda RX4 Wag	21.0	6	160	110	3.90	2.875	17.02	0	1	4	4
Datsun 710	22.8	4	108	93	3.85	2.320	18.61	1	1	4	1
Hornet 4 Drive	21.4	6	258	110	3.08	3.215	19.44	1	0	3	1
Hornet Sportabout	18.7	8	360	175	3.15	3.440	17.02	0	0	3	2
Valiant	18.1	6	225	105	2.76	3.460	20.22	1	0	3	1

The variable `mpg` would be used as a continuous variable, and the variable `cyl` would be used as a categorical variable.

### 14.1.1 Point Estimates

The first basic statistic you can compute are point estimates. These are your means, medians, etc. Here we will calculate these estimates.

#### 14.1.1.1 Mean

To obtain the mean, use the `mean()`, you only need to specify `x=` for the data to compute the mean:

```
mean(mtcars$mpg)
```

```
[1] 20.09062
```

#### 14.1.1.2 Median

To obtain the median, use the `median()`, you only need to specify `x=` for the data to compute the median:

```
median(mtcars$mpg)
```

```
[1] 19.2
```

#### 14.1.1.3 Frequency

To obtain a frequency table, use the `table()`, you only need to specify the data as the first argument to compute the frequency table:

```
table(mtcars$cyl)
```

```
 4  6  8  
11  7 14
```

#### 14.1.1.4 Proportion

To obtain the proportions for the frequency table, use the `prop.table()`. However the first argument must be the results from the `table()`. Use the `table()` inside the `prop.table()` to get the proportions:

```
prop.table(table(mtcars$cyl))
```

```
      4      6      8  
0.34375 0.21875 0.43750
```

### 14.1.2 Variability

In addition to point estimates, variability is an important statistic to report to let a user know about the spread of the data. Here we will calculate certain variability statistics.

#### 14.1.2.1 Variance

To obtain the variance, use the `var()`, you only need to specify `x=` for the data to compute the variance:

```
var(mtcars$mpg)
```

```
[1] 36.3241
```

#### 14.1.2.2 Standard deviation

To obtain the standard deviation, use the `sd()`, you only need to specify `x=` for the data to compute the standard deviation:

```
sd(mtcars$mpg)
```

```
[1] 6.026948
```

#### 14.1.2.3 Max and Min

To obtain the max and min, use the `max()` and `min()`, respectively. You only need to specify the data as the first argument to compute the max and min:

```
max(mtcars$mpg)
```

```
[1] 33.9
```

```
min(mtcars$mpg)
```

```
[1] 10.4
```

#### 14.1.2.4 Q1 and Q3

To obtain the Q1 and Q3, use the `quantile()` and specify the desired quantile with `probs=`. You only need to specify the data as the first argument and `probs=` (as a decimal) to compute the Q1 and Q3:

```
quantile(mtcars$mpg, .25)
```

```
25%  
15.425
```

```
quantile(mtcars$mpg, .75)
```

```
75%  
22.8
```

### 14.1.3 Associations

In statistics, we may be interested on how different variables are related to each other. These associations can be represented in a numerical value.

#### 14.1.3.1 Continuous and Continuous

When we measure the association between two continuous variables, we tend to use a correlation statistic. This statistic tells us how linearly associated are the variables to each other. Essentially, as one variable increases, what happens to the other variable? Does it increase (positive association) or does it decrease (negative association). To find the correlation in R, use the `cor()`. You will need to specify the `x=` and `y=` which represents vectors for each variable. Find the correlation between `mpg` and `hp` from the `mtcars` data set.

```
cor(mtcars$mpg, mtcars$hp)
```

```
[1] -0.7761684
```

#### 14.1.3.2 Categorical and Continuous

When comparing categorical variables, it becomes a bit more nuanced in how to report associations. Most of the time you will discuss key differences in certain groups. Here, we will talk about how to get the means for different groups of data. Our continuous variable is the `mpg` variable, and our categorical variable is the `cyl` variable. Both are from the `mtcars` data set. The `tapply()` allows us to split the data into different groups and then calculate different statistics. We only need to specify `X=` of the R object to split, `INDEX=` which is a list of factors

or categories indicating how to split the data set, and **FUN=** which is the function that needs to be computed. Use the `tapply()` and find the mean `mpg` for each `cyl` group: 4, 5, and 6.

```
tapply(mtcars$mpg, list(mtcars$cyl), mean)
```

```
      4      6      8
26.66364 19.74286 15.10000
```

### 14.1.3.3 Categorical and Categorical

Reporting the association between two categorical variables is may be challenging. If you have a  $2 \times 2$  table, you can report a ratio of association. However, any other case may be challenging. You can report a hypothesis test to indicate an association, but it does not provide much information about the effect of each variable. You can also report row, column, or table proportions. Here we will talk about creating cross tables and report these proportions. To create a cross table, use the `table()` and use the first two arguments to specify the two categorical variables. Create a cross tabulation between `cyl` and `carb` from the `mtcars` data set.

```
table(mtcars$cyl, mtcars$carb)
```

```
  1 2 3 4 6 8
4 5 6 0 0 0 0
6 2 0 0 4 1 0
8 0 4 3 6 0 1
```

Notice how the first argument is represented in the rows and the second argument is in the columns. Now create table proportions using both of the variables. You first need to create the table and store it in a variable and then use the `prop.table()`.

```
prop.table(table(mtcars$cyl, mtcars$carb))
```

```
      1      2      3      4      6      8
4 0.15625 0.18750 0.00000 0.00000 0.00000 0.00000
6 0.06250 0.00000 0.00000 0.12500 0.03125 0.00000
8 0.00000 0.12500 0.09375 0.18750 0.00000 0.03125
```

To get the row proportions, use the argument `margin = 1` within the `prop.table()`.

```
prop.table(table(mtcars$cyl, mtcars$carb),
             margin = 1)
```

	1	2	3	4	6	8
4	0.45454545	0.54545455	0.00000000	0.00000000	0.00000000	0.00000000
6	0.28571429	0.00000000	0.00000000	0.57142857	0.14285714	0.00000000
8	0.00000000	0.28571429	0.21428571	0.42857143	0.00000000	0.07142857

To get the column proportions, use the argument `margin = 2` within the `prop.table()`.

```
prop.table(table(mtcars$cyl, mtcars$carb),
             margin = 2)
```

	1	2	3	4	6	8
4	0.7142857	0.6000000	0.0000000	0.0000000	0.0000000	0.0000000
6	0.2857143	0.0000000	0.0000000	0.4000000	1.0000000	0.0000000
8	0.0000000	0.4000000	1.0000000	0.6000000	0.0000000	1.0000000

## 14.2 Summarizing with Tidyverse

# 15 Graphics

Through out this chapter, we use certain notations for different components in R. To begin, when something is in a gray block, `_`, this indicates that R code is being used. When I am talking about an R Object, it will be displayed as a word. For example, we will be using the R object `mtcars`. When I am talking about an R function, it will be displayed as a word followed by an open and close parentheses. For example, we will use the mean function denoted as `mean()` (read this as “mean function”). When I am talking about an R argument for a function, it will be displayed as a word following by an equal sign. For example, we will use the data argument denoted as `data=` (read this as “data argument”). When I am referencing an R package, I will use `::` (two colons) after the name. For example, in this tutorial, I will use the `ggplot2::` (read this as “ggplot2 package”) Lastly, if I am displaying R code for your reference or to run, it will be displayed on its own line. There are many components in R, and my hope is that this will help you understand what components am I talking about.

## 15.1 Base R Plotting

### 15.1.1 Introduction

This tutorial provides an introduction on how to create different graphics in R. For this tutorial, we will focus on plotting different components from the `mtcars` data set.

### 15.1.2 Contents

1. Basic
2. Grouping
3. Tweaking

### 15.1.3 Basic Graphics

Here we will use the built-in R functions to create different graphics. The main function that you will use is the `plot()`. It contains much of the functionality to create many different plots in R. Additionally, it works well for different classes of R objects. It will provide many important plots that you will need for a certain statistical analysis.

#### 15.1.4 Scatter Plot

Let's first create a scatter plot for one variable using the `mpg` variable. This is done using the `plot()` and setting the first argument `x=` to the vector.

```
plot(mtcars$mpg)
```

Notice that the x-axis is the index (which is not informative) and the y-axis is the `mpg` values.

Let's connect the points with a line. This is done by setting the `type=` to `"l"`.

```
plot(mtcars$mpg, type = "l")
```

Let's add the points back to the plot and keep the lines. What we are going to do is first create the scatter plot as we did before, but we will also use the `lines()` to add the lines. The `lines()` needs the `x=` which is a vector of points (`mpg`). The two lines of code must run together.

```
plot(mtcars$mpg)
lines(mtcars$mpg)
```

Now, let's create a more realistic scatter plot with 2 variables. This is done by specifying the `y=` with another variable in addition to the `x=` in the `plot=`. Plot a scatter plot between `mpg` and `disp`.

```
plot(mtcars$mpg,mtcars$disp)
```

Now, let's change the the axis labels and plot title. This is done by using the arguments `main=`, `xlab=`, and `ylab=`. The `main=` changes the title of the plot.

### 15.1.5 Histogram

To create a histogram, use the `hist()`. The `hist()` only needs `x=` which is numerical vector. Create a histogram with the `mpg` variable.

```
hist(mtcars$mpg)
```

If you want to change the number of breaks in the histogram, use the `breaks=`. Create a new histogram of the `mpg` variable with ten breaks.

```
hist(mtcars$mpg, breaks = 10)
```

The above histograms provide frequencies instead of relative frequencies. If you want relative frequencies, use the `freq=` and set it equal to `FALSE` in the `hist()`.

```
hist(mtcars$mpg, freq = FALSE)
```

#### 15.1.6 Density Plot

A density plot can be used instead of a histogram. This is done by using the `density()` to create an object containing the information to create density function. Then, use the `plot()` to display the plot. The only argument the `density()` needs is the `x=` which is the data to be used. Create a density plot the `mpg` variable.

```
plot(density(mtcars$mpg))
```

**density.default(x = mtcars\$mpg)**

N = 32 Bandwidth = 2.477

Now, if we want to overlay the density function over a histogram, use the `lines()` with the output from the `density()` as its main input. First create the histogram using the `hist()` and setting the `freq=` to `FALSE`. Then use the `lines()` to overlay the density. Make sure to run both lines together.

```
hist(mtcars$mpg, freq = FALSE)  
lines(density(mtcars$mpg))
```

**Histogram of mtcars\$mpg**

### 15.1.7 Box Plots

A commonly used plot to display relevant statistics is the box plot. To create a box plot use the `boxplot()`. The function only needs the `x=` which specifies the data to create the box plot. Use the box plot function to create a box plot on for the variable `mpg`.

```
boxplot(mtcars$mpg)
```

If you want to make the box plot horizontal, use `horizontal=` and set it equal to `TRUE`.

```
boxplot(mtcars$mpg, horizontal = TRUE)
```

### 15.1.8 Bar Chart

A histogram shows you the frequency for a continuous variable. A bar chart will show you the frequency of a categorical or discrete variable. To create a bar chart, use the `barplot()`. The main argument it needs is the `height=` which needs to an object from the `table()`. Create a bar chart for the `cyl` variable.

```
barplot(table(mtcars$cyl))
```

### 15.1.9 Pie Chart

While I do not recommend using a pie chart, R is capable of creating one using the `pie()`. It only needs the `x=` which is a vector numerical quantities. This could be the output from the `table()`. Create a pie chart with the `cyl` variable.

```
pie(table(mtcars$cyl))
```

### 15.1.10 Grouping

Similar to obtaining statistics for certain groups, plots can be grouped to reveal certain trends. We will look at a couple of methods to visualize different groups.

#### 15.1.10.1 One Variable Grouping

Two ways to display groups is by using color coding or panels. I will show you what I think is the best way to group variables. There may be better ways to do this, such as using the

ggplot2 package. Before we begin, create three new R objects that are a subset of the `mtcars` data set into 3 different data sets with for the three different values of the `cyl` variable: “4”, “6”, and “8”. use the `subset()` to create the different data sets. Name the new R objects `mtcars_4`, `mtcars_6`, and `mtcars_8`, respectively.

```
mtcars_4 <- subset(mtcars, cyl == 4)
mtcars_6 <- subset(mtcars, cyl == 6)
mtcars_8 <- subset(mtcars, cyl == 8)
```

#### 15.1.10.1.1 Scatter Plot

To create different colors points for their respective label associated `cyl` variable. First create a base scatter plot using the `plot()` to set up the plot. Then one by one, overlay a set of new points on the base plot using the `points()`. The first two arguments should be the vectors of data from their respective R object subset. Also, use the `col=` to change the color of the points. The `col=` takes either a string or a number.

```
plot(mtcars$mpg, mtcars$disp)
points(mtcars_4$mpg, mtcars_4$disp, col = "red")
points(mtcars_6$mpg, mtcars_6$disp, col = "blue")
points(mtcars_8$mpg, mtcars_8$disp, col = "green")
```

#### 15.1.10.1.2 Histogram

Now, it is more difficult to overlay histograms on a plot of different colors. Therefore, a panel approach may be more beneficial. This can be done by setting up R to plot a grid of plots. To do this, use the `par()` to tell R how to set up the grid. Then use the `mfrow=`, which is

a vector of length two, to set up a grid. The `mfrow=` usually has an input of `c(ROWS, COLS)` which states the number of rows and the number of columns. Once this is done, the next plots you create will be used to populate the grid.

```
par(mfrow=c(1,3))
hist(mtcars_4$mpg)
hist(mtcars_6$mpg)
hist(mtcars_8$mpg)
```

Histogram of mtcars\_4\$mpg Histogram of mtcars\_6\$mpg Histogram of mtcars\_8\$mpg

Every time you use the `par()`, it will change how graphics are created in an R session. Therefore, all your plots will follow the new graphic parameters. You will need to reset it by typing `dev.off()`.

### 15.1.10.1.3 Bar Chart

To visualize two categorical variables, we can use a color-coded bar chart to compare the frequencies of the categories. This is simple to do with the `barplot()`. First, use the `table()` to create a cross-tabulation of the frequencies for two variables. Then use the `boxplot()` to visualize both variables. Then use `legend=` to create a label when the bar chart is color-coded. Additionally, use the `beside=` argument to change how the plot looks. Use the code below to compare the variables `cyl` and `am` variable.

```
barplot(table(mtcars$cyl, mtcars$am), beside = TRUE, legend = rownames(table(mtcars$cyl, m
```

Notice that I use the `rownames()` to label the legend.

### 15.1.11 Tweaking

#### 15.1.11.1 Labels

The main tweaking of plots I will talk about is changing the the axis label and titles. For the most part, each function allows you to use the `main=`, `xlab=`, and `ylab=`. The `main=` allows you to change the title. The `xlab=` and `ylab=` allow you to change the labels for the x-axis and y-axis, respectively. Create a scatter plot for the variables `mpg` and `disp` and change the labels.

```
plot(mtcars$mpg, mtcars$disp, main = "MPG vs Displacement", xlab = "MPG", ylab = "Displacement")
```

## MPG vs Displacement

## 15.2 ggplot2

### 15.2.1 Introduction

The `ggplot2::` provides a set of functions to create different graphics. For more information on plotting in `ggplot2::`, please visit the this excellent [resource](#). Here we will discuss some of the basics to the `ggplot2::`. To me, `ggplot2::` creates a plot by adding layers to a base plot. The syntax is designed for you to change different components of a plot in an intuitive manner. For this tutorial, we will focus on plotting different components from the `mpg` data set.

#### 15.2.1.1 Contents

1. Basic
2. Grouping
3. Themes/Tweaking

### 15.2.2 Basics

To begin, the `ggplot2::` really works well when you are using data frames. If you have any output that you want to plot, convert into to a data frame. Once we have our data set, the first thing you would want to do is specify the main components of your base plot. This will

be what will be plotted on your x-axis, and what will be plotted on your y-axis. Next, you will create the type of plot. Lastly, you will add different layers to tweak the plot for your needs. This can be changing the layout or even overlaying another plot. The 'ggplot2::' provides you with tools to do almost everything you need to create a plot easily.

Before we begin plotting, load the `ggplot2::` in R.

```
library(ggplot2)
```

Now, when we create a base plot, we will use the `ggplot()`. This will initialize the data that we need to use with the `data=` and how to map it on the x and y axis with the `mapping=`. With the `mapping=`, you will need to use the `aes()` which constructs the mapping function for the base plot. The `aes()` requires the `x=` and optionally uses the `y=` to set which values represents the x and y axis. The `aes()` also accepts other arguments for grouping or other aesthetics.

Before we begin, create a new variable in `mtcars` called `ind` and place a numeric vector which contains integers from 1 to 32.

```
mtcars$ind <- c(1:32)
```

Now, let's create the base plot and assign it to `gg_1`. Use the `ggplot()` and set `mtcars` as its data and the variable `ind` as `x=` and `mpg` as the `y=`

```
gg_1 <- ggplot(mtcars, aes(ind, mpg))
```

This base plot is now used to create certain plots. Plots are created by adding functions to the base plot. This is done by using the `+` operator and then a specific `ggplot2::` function. Below we will go over some of the functions necessary.

### 15.2.3 Scatter Plot

To create a scatter plot in `ggplot2::`, add the `geom_point()` to the base plot. You do not need to specify any arguments in the function. Create a scatter plot to `gg_1`

```
gg_1 + geom_point()
```

If we want to put lines instead of points, we will need to use the `geom_point()`. Change the points to a line.

```
gg_1 + geom_line()
```

To overlay points to the plot, add `geom_point()` as well as `geom_line()`. Add points to the plot above.

```
gg_1 + geom_point() + geom_line()
```

To create a 2 variable scatter plot. You will just need to specify the `x=` and `y=` in the `aes()`. Create a base plot using the `mtcars` data set and use the `mpg` and `disp` as the x and y variables, respectively, and assign in it to `gg_2`

```
gg_2 <- ggplot(mtcars, aes(mpg, disp))
```

Now create a scatter plot using `gg_2`.

```
gg_2 + geom_point()
```

#### 15.2.4 Histogram and Density Plot

To create a histogram and density plots, create a base plot and specify the variable of interest in the `aes()`, only specify one variable. Create a base plot using the `mtcars` data set and the `mpg` variable. Assign it to `gg_3`.

```
gg_3 <- ggplot(mtcars, aes(mpg))
```

To create a histogram, use the `geom_histogram()`.

```
gg_3 + geom_histogram()
```

``stat_bin()`` using ``bins = 30``. Pick better value with ``binwidth``.

The above plot shows a histogram, but the number of bins is quite large. We can change the bin width argument, `binwidth=`, the the `geom_histogram()`. Change the bin width to seven.

```
gg_3 + geom_histogram(binwidth = 7)
```

#### 15.2.4.1 Density Plot

To create a density plot, use the `geom_density()`. Create a density plot for the `mpg` variable.

```
gg_3 + geom_density()
```

#### 15.2.4.2 Both

Similar to adding lines and points in the same plot, you can add a histogram and a density plot by adding both the `geom_histogram()` and `geom_density()`. However, in the `geom_histogram()`, you must add `aes(y=..density..)` to create a frequency histogram. Create a plot with a histogram and a density plot.

```
gg_3 + geom_histogram(aes(y=..density..), bins=7) +  
  geom_density()
```

Warning: The dot-dot notation (`..density..`) was deprecated in ggplot2 3.4.0.  
i Please use `after_stat(density)` instead.

### 15.2.5 Box Plots

If you need to create a box plot, use the `stat_boxplot()`. Create a boxplot for the variable `mpg`. All you need to do is add `stat_boxplot()`.

```
gg_3 + stat_boxplot()
```

### 15.2.6 Bar Charts

Creating a bar chart is similar to create a box plot. All you need to do is use the `stat_count()`. First create a base plot using the `mtcars` data sets and the `cyl` variable for the mapping and assign it to `gg_4`.

```
gg_4 <- ggplot(mtcars, aes(cyl))
```

Now create the bar plot by adding the `stat_count()`.

```
gg_4 + stat_count()
```

## 15.2.7 Grouping

The ‘ggplot2::’ easily allows you to create plots from different groups. We will go over some of the arguments and functions to do this.

### 15.2.7.1 One Variable Grouping

#### 15.2.7.1.1 Scatter Plot

To begin, we want to specify the grouping variable within the `aes()` with the `color=`. Additionally, the argument works best with a factor variable, so use the `factor()` to create a factor variable. Create a base plot from the `mtcars` data set using `mpg` and `disp` for the x and y axis, respectively, and set the `color=` equal to the `factor(cyl)`. Assign it the R object `gg_5`.

```
gg_5 <- ggplot(mtcars, aes(mpg, disp, color=factor(cyl)))
```

Once the base plot is created, ‘ggplot2::’ will automatically group the data in the plots. Create the scatter plot from the base plot.

```
gg_5 + geom_point()
```

If you want to change the shapes instead of the color, use the `shape=`. Create a base plot from the `mtcars` data set using `mpg`, and `disp` for the x and y axis, respectively, and group it by `cyl` with the `shape=`. Assign it the R object `gg_6`.

```
gg_6 <- ggplot(mtcars, aes(mpg, disp, shape=factor(cyl)))  
gg_6 + geom_point()
```

### 15.2.7.1.2 Histograms

Histograms can be grouped by different colors. This is done by using the `fill=` within the `aes()` in the base plot. Assign it the R object `gg_7`.

```
gg_7 <- ggplot(mtcars, aes(mpg, fill = factor(cyl)))
```

Now create a histogram from the base plot `gg_7`.

```
gg_7 + geom_histogram(bins = 6, alpha = 0.3)
```

Sometimes we would like to view the histogram on separate plots. The `facet_wrap()` and the `facet_grid()` allows this. Using either function, you do not need to specify the grouping factor in the `aes()`. You will add `facet_wrap()` to the plot. It needs a formula argument with the grouping variable. Using the R object `gg_3` create side by side plots using the `cyl` variable. Remember to add `geom_histogram()`.

```
gg_3+geom_histogram() + facet_wrap( ~ cyl)
```

``stat_bin()`` using ``bins = 30``. Pick better value with ``binwidth``.

### 15.2.7.1.3 Density Plot

Similar to histograms, density plots can be grouped by variables the same way. Using `gg_7`, create color-coded density plots. All you need to do is add `geom_density()`.

```
gg_7 + geom_density(alpha=0.3)
```

Using `gg_3`, create side by side density plots. You need to do is add `geom_density()` and `facet_wrap()` to group with the `cyl` variable.

```
gg_3 + geom_density() + facet_wrap( ~ cyl)
```

#### 15.2.7.1.4 Bar Chart

To create a side by side bar plot, you can use the `facet_wrap()` with a grouping variable. Using `gg_4`, create a side by side bar plot using `vs` as the grouping variable. Remember to add `stat_count()` as well.

```
gg_4 + stat_count() + facet_wrap(~vs)
```

If you want to compare the bars from different group in one plot, you can use the `fill=` from the `aes()`. The `fill=` just needs a factor variable (use `factor()`). First create a base plot using the data `mtcars`, variable `cyl` and grouping variable `vs`. Assign it to `gg_8`.

```
gg_8 <- ggplot(mtcars, aes(cyl, fill = factor(vs)))
```

Now create a bar chart by adding `stat_count()`.

```
gg_8 + stat_count()
```

If you want grouping bars to be side by side, use the `position=` in the `stat_count()` and set it equal to "dodge". Create the bar plot using the `position = "dodge"`.

```
gg_8 + stat_count(position = "dodge")
```

## 15.2.8 Themes/Tweaking

In this section, we will talk about the basic tweaks and themes to `ggplot2::`. However, `ggplot2::` is much more powerful and can do much more. Before we begin, let's look at object `gg_9` to understand the plot. To view a plot, use the `plot()`.

```
plot(gg_9)
```

### 15.2.8.1 Title

To change the title, add the `ggtitle()` to the plot. Put the new title in quotes as the first argument. Change the title for `gg_9`.

```
gg_9 + ggtitle("Scatter Plot")
```

#### 15.2.8.2 Axis

Changing the labels for a plot, add the `xlab()` and `ylab()`, respectively. The first argument contains the phrase for the axis. Change the axis labels for `gg_9`.

```
gg_9 + xlab("MPG") + ylab("Displacement")
```

### 15.2.8.3 Themes

If you don't like how the plot looks, `ggplot2::` has custom themes you can add to the plot to change it. These functions usually are formatted as `theme_*`, where the `*` indicates different possibilities. I personally like how `theme_bw()` looks. Change the theme of `gg_9`.

```
gg_9 + theme_bw()
```

Additionally, you can change certain part of the theme using the `theme()`. I encourage you to look at what are other possibilities.

### 15.2.9 Saving plot

If you want to save the plot, use the `ggsave()`. Read the help documentation for the functions capabilities.
